

## FEATURES

- Filterless, digital input Class-D amplifier
- Serial digital audio interface supports common formats
  - I<sup>2</sup>S, left justified, right justified, TDM1-16, and PCM
- 2 channels × 2 W into 4 Ω and 2 channels × 1.4 W into 8 Ω
  - with 1% THD+N, when using a 5 V supply
- I<sup>2</sup>C control interface or standalone operation
- 91% efficiency at full scale into an 8 Ω load
- 97 dB signal-to-noise ratio (SNR), A-weighted
- 80 dB power supply rejection ratio (PSRR) at 217 Hz
- Digital volume control: -71.25 dB to +24 dB in 0.375 dB steps
- Supports a wide range of sample rates from 8 kHz to 96 kHz
- Automatic sample rate detection
- Can operate using 64 × f<sub>s</sub> BCLK as the MCLK source
- 2.5 V to 5.5 V speaker supply voltage (PVDD)
- 1.62 V to 3.6 V digital supply voltage (DVDD)
- Pop-and-click suppression
- Short-circuit and thermal protection with programmable autorecovery
- Smart power-down when no input signal is detected
- Power-on reset
- Low power modes for performance/power trade-offs
- User selectable ultralow EMI emission mode
- Programmable dynamic range compression (DRC) with noise gate, expander, compressor, and limiter
- Available in two packages
  - 16-bump, 2.2 mm × 2.2 mm, 0.5 mm pitch WLCSP
  - 20-lead, 4.0 mm × 4.0 mm LFCSP

## APPLICATIONS

- Mobile phones
- Portable media players
- Laptop PCs
- Wireless speakers
- Portable gaming
- Small LCD televisions
- Navigation systems

## GENERAL DESCRIPTION

The [SSM2518](#) is a digital input, Class-D power amplifier that combines a digital-to-analog converter (DAC) and a sigma-delta ( $\Sigma$ - $\Delta$ ) Class-D modulator. This unique architecture enables extremely low real-world power consumption from digital audio sources with excellent audio performance. The [SSM2518](#) is ideal for power sensitive applications, such as mobile phones and portable media players, where system noise can corrupt small analog signals such as those sent to an analog input audio amplifier.

Using the [SSM2518](#), audio data can be transmitted to the amplifier over a standard digital audio serial interface, thereby significantly reducing the effect of noise sources such as GSM interference or other digital signals on the transmitted audio. The closed-loop digital input design retains the benefits of an all digital amplifier, yet enables very good PSRR and audio performance. The three level,  $\Sigma$ - $\Delta$  Class-D modulator is designed to provide the least amount of EMI interference, the lowest quiescent power dissipation, and the highest audio efficiency without sacrificing audio quality.

Input is provided via a serial audio interface, programmable to accept all common audio formats including I<sup>2</sup>S and TDM. Control of the IC is provided via an I<sup>2</sup>C control interface. The [SSM2518](#) can accept a variety of input MCLK frequencies and can use BCLK as the clock source in some configurations.

Additional features include a soft digital volume control, de-emphasis, and a programmable digital dynamic range compressor.

The architecture of the [SSM2518](#) provides a solution that offers lower power and higher performance than existing DAC plus Class-D solutions. Its digital interface also offers a better system solution for other products whose sole audio source is digital, such as wireless speakers, laptop PCs, portable digital televisions, and navigation systems.

<sup>1</sup> Typical value given for 48 kHz sample rate.

**DIGITAL TIMING**

All timing specifications are given for the default setting (I<sup>2</sup>S mode) of the serial input port.

Table 5.

Parameter	Limit		Unit	Description
	Min	Max		
<b>MASTER CLOCK</b>				
t <sub>MP</sub>	74	136	ns	MCLK period, 256 × f <sub>s</sub> mode (MCS = b0010)
t <sub>MP</sub>	148	271	ns	MCLK period, 128 × f <sub>s</sub> mode (MCS = b0001)
<b>SERIAL PORT</b>				
t <sub>BIL</sub>	40		ns	BCLK low pulse width
t <sub>BIH</sub>	40		ns	BCLK high pulse width
t <sub>LIS</sub>	10		ns	Setup time from LRCLK or SDATA edge to BCLK rising edge
t <sub>LH</sub>	10		ns	Hold time from BCLK rising edge to LRCLK or SDATA edge
t <sub>SIS</sub>	10		ns	SDATA setup time to BCLK rising
t <sub>SIH</sub>	10		ns	SDATA hold time from BCLK rising
<b>I<sup>2</sup>C PORT</b>				
f <sub>SCL</sub>		400	kHz	SCL frequency
t <sub>SCLH</sub>	0.6		μs	SCL high
t <sub>SCLL</sub>	1.3		μs	SCL low
t <sub>SCS</sub>	0.6		μs	Setup time; relevant for repeated start condition
t <sub>SCH</sub>	0.6		μs	Hold time; after this period, the first clock is generated
t <sub>DS</sub>	100		ns	Data setup time
t <sub>SCR</sub>		300	ns	SCL rise time
t <sub>SCF</sub>		300	ns	SCL fall time
t <sub>SDR</sub>		300	ns	SDA rise time
t <sub>SDF</sub>		300	ns	SDA fall time
t <sub>BFT</sub>	0.6		μs	Bus-free time (time between stop and start)

**ABSOLUTE MAXIMUM RATINGS**

Absolute maximum ratings apply at 25°C, unless otherwise noted.

**Table 6.**

Parameter	Rating
PVDD Supply Voltage	−0.3 V to +6 V
DVDD Supply Voltage	−0.3 V to +3.6 V
Input Voltage (ADDR, MCLK, BCLK, LRCLK, SDATA, SAMOD Pins)	−0.3 V to +3.6 V
Input Voltage ( $\overline{SD}$ , SDA, and SCL Pins)	−0.3 V to +6 V
ESD Susceptibility	4 kV
Storage Temperature Range	−65°C to +150°C
Operating Temperature Range	−40°C to +85°C
Junction Temperature Range	−65°C to +165°C
Lead Temperature (Soldering, 60 sec)	300°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

**THERMAL RESISTANCE**

$\theta_{JA}$  is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.

**Table 7. Thermal Resistance**

Package Type	$\theta_{JA}$	Unit
16-ball, 2 mm × 2 mm WLCSP	56	°C/W
20-lead, 4.0 mm × 4.0 mm LFCSP	54	°C/W

**ESD CAUTION**

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

## THEORY OF OPERATION

The **SSM2518** is fully integrated 2-channel digital input, Class-D output audio amplifier. The **SSM2518** receives digital audio input and produces the PDM differential switching outputs using the internal power stage. The part has built in protection for over-temperature as well as overcurrent conditions. The **SSM2518** also has built in soft turn on and soft turn off for pop-and-click suppression. The part has programmable register control via the I<sup>2</sup>C port.

### POWER SUPPLIES

The **SSM2518** requires two power supplies: PVDD and DVDD. Descriptions of each of these supplies follow.

#### PVDD

The PVDD pin supplies power to the full bridge power stage of a MOSFET and its associated drive, control, and protection circuitry. PVDD can operate from 2.5 V to 5.5 V and must be present to obtain audio output. Lowering the supply PVDD results in lower output power and, correspondingly, lower power consumption but does not degrade audio performance.

#### DVDD

The DVDD pin provides power to the digital logic circuitry and determines the input trip points. DVDD can operate from 1.62 V to 3.6 V and must be present to obtain audio output. Lowering the supply voltage of DVDD results in lower power consumption but does not affect audio performance.

### POWER-DOWN MODES

The **SSM2518** offers a hardware shutdown pin,  $\overline{\text{SD}}$ , which can be used to set the IC to its lowest power state, with all blocks disabled. This hardware shutdown mode is enabled when the  $\overline{\text{SD}}$  pin is pulled low.

When the hardware shutdown is removed, the IC begins in software power-down mode, where all blocks except for the I<sup>2</sup>C interface are disabled. To fully power up the amplifier, clear S\_RST (Bit 7 of Register 0x00). In addition to the software power-down, the software master mute is enabled at the initial state of the amplifier; therefore, no audio is output until Bit 0 of Register 0x07 is cleared.

The left and right channels can be independently shut down by setting setting L\_PWDN and R\_PWDN (Bit 1 and Bit 2, respectively, in Register 0x09). Disabling a channel shuts down the channel specific digital processing, DAC, Class-D modulator, and power stage.

The **SSM2518** also contains a smart power-down feature, which is enabled by default. This feature can be disabled by clearing APWDN\_EN (Bit 0 in Register 0x09). When active, this feature

monitors the incoming digital audio signal. If this is zero for 1024 consecutive samples, regardless of sample rate, it puts the IC in the smart power-down state wherein all blocks, except the I<sup>2</sup>S and I<sup>2</sup>C ports, are placed in a low power state. Once a single nonzero input is received on the I<sup>2</sup>S interface, the **SSM2518** leaves this state and resumes normal operation.

### POWER-ON RESET/VOLTAGE SUPERVISOR

The **SSM2518** includes an internal power-on reset and voltage supervisor circuit. This circuit provides an internal reset to all circuitry whenever PVDD or DVDD is substantially below the nominal operating threshold. This circuit simplifies supply sequencing during initial power-on.

The circuit also monitors the power supplies to the **SSM2518**. If the supply voltages fall below the nominal operating threshold, this circuit stops the output and issues a reset. This ensures that no damage occurs due to low voltage operation and that no pops can occur under nearly any power removal condition.

### MASTER AND BIT CLOCK

The **SSM2518** requires an internal master clock to operate. This clock must run at a frequency between 2.048 MHz and 6.144 MHz, depending on the input sample rate, and it must be fully synchronous with the incoming audio data. This clock signal can be derived from either the MCLK or BCLK pin, depending on the configuration used.

If the MCLK pin is used, the internal clock is derived by either dividing, passing through, or doubling the external clock signal as required. The clock supplied to the MCLK pin can range from 2.048 MHz to 38.864 MHz. In this case, the external MCLK pin signal can run at various multiples of the audio sample rate ( $f_s$ ). The relationship between the MCLK rate and the audio sample rate is determined by the master clock select (MCS) register setting, Bits[4:1] in Register 0x00. Table 11 provides a summary of the available options.

In addition, a bit clock must run at the same rate as the incoming audio data on the SDATA pin. This clock can be supplied to the BCLK pin, or it can be generated internally by dividing MCLK. In this case, when BCLK\_GEN (Bit 7 of Register 0x03) is set, the logic level of the BCLK pin is used to select the audio interface BCLK rate. Tie the BCLK pin to DVDD for 16 clock cycles per channel; tie it to ground for 32 cycles per channel.

If the system bit clock is in the range of acceptable internal master clock frequencies (between 2.048 MHz and 6.144 MHz), then it can serve as both master clock and bit clock. Setting NO\_BCLK (Bit 5 of Register 0x00) routes the signal on the

MCLK pin to serve as the internal bit clock as well. In this case, tie the BCLK pin to ground.

Once the SSM2518 has entered its power-down state, it is possible to gate the clocks to conserve system power. However, a valid master clock must be present for the audio amplifier to operate. It is best to use a low jitter clock (less than 1 ns peak-to-peak) to ensure the specified audio performance.

TYPICAL APPLICATION CIRCUIT

\*OPTIONAL FOR APPLICATIONS WITH >20cm SPEAKER CABLE.

Figure 24. Typical Application Circuit Using I<sup>2</sup>C Configuration

10242-039

## DIGITAL AUDIO INTERFACE

The SSM2518 operates as a slave on the serial audio interface. It is capable of receiving stereo I<sup>2</sup>S-style, left justified, or right justified data. Mono, stereo, and multichannel PCM/TDM interface formats are available. The data format and interface style are selected by adjusting the SDATA\_FMT and SAI fields in Register 0x02. Note that, when operating in right justified mode, the proper data width must be chosen. The function of the LRCLK pin varies depending on the data format. See Figure 26 through Figure 30 for the expected audio formats for various configurations.

### CHANNEL MAPPING

Stereo audio formats and TDM formats with 2, 4, 8, or 16 channels are available. In these modes, the amplifier left and right audio can be independently chosen from any of the available channels using the two fields in Register 0x04. For most digital interface formats, many of these options are not present. For example, in stereo modes, only Channel 0 and Channel 1 are valid, and in four-slot TDM mode, only Channel 0, Channel 1, Channel 2, and Channel 3 are valid.

### SAMPLE RATE DETECTION

The SSM2518 can be configured to automatically detect the sample rate, or the sample rate can be entered manually into the FS field (Bit 1 and Bit 0 of Register 0x02). The choice of automatic or manual sample rate detection is made by setting the ASR bit (Bit 0 of Register 0x01). Sample rate detection functions properly only when MCS (Bits[4:1] of Register 0x00) is set correctly.

### STANDALONE MODE

When the SAMOD pin is pulled high, the SSM2518 can operate in several common stereo formats without any I<sup>2</sup>C control. Some details of the serial audio interface can be configured by tying the unused I<sup>2</sup>C pins to ground or DVDD, as shown in Table 10. In addition, the amplifier gain can be controlled via the ADDR pin.

Table 10. Standalone Mode Pin Functions

Pin	Standalone Function	Pin Options
SCL	FORMAT	Low: I <sup>2</sup> S High: left justified
SDA	MCLK_SEL	Low: MCLK = 256 × f <sub>s</sub> High: MCLK = 384 × f <sub>s</sub>
$\overline{\text{SD}}$	$\overline{\text{SD}}$	Low: shutdown/mute High: normal operation
ADDR	GAIN	Low: +12 dB digital gain High: 0 dB digital gain

In standalone mode, the volume control, dynamic range control, and EMI control features are disabled. Automatic sample rate detection and smart power-down are enabled. All other settings are set to their default values.

### LOW POWER MODES

Two low power modes are available. If DAC\_LPM (Bit 3 of Register 0x09) is set, the digital-to-analog converter (DAC) runs at half speed, reducing the quiescent current. This half speed mode is also active when the MCS setting (Bits[4:1] of Register 0x00) is set to its lowest value (MCS = 0000) because the slowest acceptable MCLK rates can only support half speed DAC operation.

If AMP\_LPM (Bit 4 of Register 0x09) is set, the  $\Sigma$ - $\Delta$  modulator runs in a special mode that offers lower quiescent current when the output power is small, at the expense of slightly degraded audio performance.

### DYNAMIC RANGE CONTROL

The dynamic range control, or DRC, can be used to reduce the dynamic range of the audio signal. A common DRC scheme involves applying a gain reduction to large output signals, along with a net increase in gain for moderate to small signals. The qualitative result is a louder speaker output for moderate output levels without the undesired effects of amplifier clipping or speaker overdrive at high levels.

To calculate the gain adjustment, an rms detector gives the average level of the input signal, based on the averaging time set by RMS\_TAV (Bits[3:0] in Register 0x12). Based on this time averaged level, the overall gain is adjusted so that the input/output characteristic matches the specified compression curve. This curve can be represented by a log-to-log graph with five distinct regions, as shown in Figure 25.

Figure 25. DRC Compression Curve: Log-to-Log Representation of the DRC Output Level vs. Input Level

From bottom left to top right, these regions (shown in red) are the noise gate, expander, linear region, compressor, and limiter. The control points between these regions can be set using the DRC control registers (Register 0x0A through Register 0x12) using the variable names (CT, ET, and so forth) as shown on the plot axes in Figure 25. Each element can be individually enabled using the LIM\_EN, COMP\_EN, EXP\_EN, and NG\_EN bits in

Register 0x0A. The entire DRC function can be enabled or disabled using DRC\_EN (Bits[1:0] of Register 0x0A).

### Linear Region

For input amplitudes between the DRC\_ET and DRC\_CT thresholds, the DRC attenuation is set to zero, that is, the input is passed straight through to the output. This is the region in the center of the compression curve (see Figure 25) with a 1:1 slope, where the input and output amplitude are the same.

### Compressor

Above the input level set by DRC\_CT (Bits[3:0] of Register 0x0C), the output amplitude does not rise as quickly as the input. This provides a smooth transition to the limiter region, where the output stops increasing altogether at the input level set by DRC\_LT (Bits[7:4] of Register 0x0C). At this point, the output level is DRC\_SMAX (Bits[7:4] of Register 0x0E).

### Limiter

When the input level is above the input level set by DRC\_LT, the output level does not exceed the level given by DRC\_SMAX (Bits[7:4] of Register 0x0E). Instead, the overall gain is reduced to maintain that level without clipping.

### Expander

When the expander is enabled and the input level falls below the level set by DRC\_ET (Bits[7:4] of Register 0x0D), the output level begins to decrease more rapidly than the input. This provides a smooth transition to the noise gate, where sufficiently small signals are blocked completely.

When the input signal falls to the level set by DRC\_NT (Bits[3:0] of Register 0x0D), the output level is set by DRC\_SMIN (Bits[3:0] of Register 0x0E).

### Noise Gate

When the noise gate is enabled and the input signal level falls below the threshold set by DRC\_NT for a period of time, the output is set to zero. Set this at a level lower than all signals of interest to block the output in periods of silence.

The period of time for which the input level must remain below the noise gate threshold prior to the output setting to zero is determined by HDT\_NG, Bits[3:0] of Register 0x10.

### Attack and Decay Rates

To prevent audible distortion effects as the gain changes, the time constants for the attack (gain reduction) and decay (gain increase) are adjustable. The attack time is set by DRC\_ATT (Bits[7:4] of Register 0x0F), and the decay time is set by DRC\_DEC (Bits[3:0] of Register 0x0F).

Between attack and decay, a hold time is used to prevent rapid switching between increased gain and decreased gain. The hold time is set by HDT\_NOR (Bits[7:4] of Register 0x10).

### Post-DRC Gain

Because the DRC feature may have an overall effect on the system gain, a separate digital gain option is provided to allow

the user to compensate for this effect. This digital gain option is independent of the volume control feature, allowing an overall gain adjustment that remains separate from the volume settings. This level is set by DRC\_POST\_G (Bits[5:2] of Register 0x11).

Depending on the application, the entire DRC block can be placed before or after the volume controls (L\_VOL and R\_VOL). This option is set by PRE\_VOL (Bit 6 of Register 0x0A).

### MUTE OPTIONS

Several mute options are available. Each channel can be muted independently using the left channel mute (L\_MUTE, Bit 1 of Register 0x07) or the right channel mute (R\_MUTE, Bit 2 of Register 0x07). Alternatively, both channels can be muted simultaneously using the master mute option (M\_MUTE, Bit 0 of Register 0x07).

The master mute is enabled at system startup; therefore, it must be disabled before any audio is produced.

The SSM2518 also contains an automatic mute feature. This feature is enabled by setting AMUTE (Bit 7 of Register 0x07). When active, this feature monitors the incoming digital audio signal. When the data stream is zero for 2048 consecutive frames (1024 stereo samples), the output is muted. When a single nonzero input is received on the I<sup>2</sup>S interface, the SSM2518 is unmuted and resumes normal operation.

### VOLUME CONTROL

The SSM2518 has a digital volume control that allows independent control of the left and right channels via Registers 0x05 and 0x06, respectively. 255 levels are available, providing a range from +24 dB to -71.25 dB in 0.375 dB increments. This is a soft volume control, meaning that the gain is adjusted continuously from one value to another. This continuously adjusted gain prevents the audible pop that occurs with an instantaneous gain adjustment.

When VOL\_LINK (Bit 3 in Register 0x07) is set, both channels are linked to the left channel volume setting.

### DE-EMPHASIS FILTER

A digital de-emphasis filter is provided to compensate for the standard compact disc style preemphasis, which occurs in some audio systems. This filter is designed for use with a 44.1 kHz sample rate only. To enable the de-emphasis filter, set DEEMP\_EN (Bit 4 of Register 0x07).

### ANALOG GAIN

The analog gain of the SSM2518 amplifier is set by ANA\_GAIN (Bit 5 of Register 0x07). Each gain setting is designed to match the scaling needed for a specified PVDD voltage so that the digital full-scale values correspond to the clipping points of the amplifier at that voltage.

If PVDD is larger than the voltage specified in this register, the digital scale does not fill the output voltage range and maximum output power is reduced. Similarly, if PVDD is smaller than

specified in this register, analog clipping may occur within the range of possible digital codes.

### FAULT DETECTION AND RECOVERY

Three fault conditions are detected by the [SSM2518](#) fault detection system: left channel overcurrent, right channel overcurrent, and overtemperature. When any of these is detected, the amplifier shuts down and a read-only I<sup>2</sup>C bit is set to indicate the cause of the shutdown. The OC\_L, OC\_R, and OT fault indicators are Bit 7, Bit 6, and Bit 5 (respectively) of Register 0x08.

An autorecovery feature can be enabled for temperature faults, current faults, or both, depending on the state of ARCV (Bit 1 and Bit 0 of Register 0x08).

If autorecovery is enabled, the amplifier waits a short time (10 ms, 20 ms, 40 ms, or 80 ms) and attempts to recover. The recovery delay is set by AR\_TIME (Bit 7 and Bit 6 of Register 0x09). The maximum number of consecutive recovery attempts can be set to one, three, seven, or unlimited attempts; this number is set by MAX\_AR (Bit 3 and Bit 2 of Register 0x08).

If the autorecovery feature is disabled or the maximum number of attempts has been reached, the amplifier remains shut down until a software reset or manual fault recovery attempt occurs. The manual fault recovery is triggered by setting the write-only bit, MRCV (Bit 4 of Register 0x08).

## I<sup>2</sup>C CONFIGURATION INTERFACE

### OVERVIEW

The **SSM2518** supports a 2-wire serial (I<sup>2</sup>C-compatible) micro-processor bus driving multiple peripherals. Two pins, serial data (SDA) and serial clock (SCL), carry information between the **SSM2518** and the system I<sup>2</sup>C master controller. The **SSM2518** is always a slave on the bus, meaning it cannot initiate a data transfer. Each slave device is recognized by a unique device address. The device address byte format is shown in Figure 31. The address resides in the first seven bits of the I<sup>2</sup>C write. The LSB of this byte sets either a read or write operation.

Logic Level 1 corresponds to a read operation, and Logic Level 0 corresponds to a write operation. The full byte addresses are shown in Figure 3, where the subaddresses are automatically incremented at word boundaries and can be used for writing large amounts of data to contiguous memory locations. This increment happens automatically after a single word write unless a stop condition is encountered. A data transfer is always terminated by a stop condition.

Both SDA and SCL should have a 2.2 kΩ pull-up resistor on the lines connected to them.

BIT 0	BIT 1	BIT 2	BIT 3	BIT 4	BIT 5	BIT 6	BIT 7
0	1	1	0	1	ADDR	0	R/W

Figure 31. I<sup>2</sup>C Device Address Byte Format

### Addressing

Initially, each device on the I<sup>2</sup>C bus is in an idle state, monitoring the SDA and SCL lines for a start condition and the proper address. The I<sup>2</sup>C master initiates a data transfer by establishing a start condition, defined by a high-to-low transition on SDA while SCL remains high. This indicates that an address/data stream follows. All devices on the bus respond to the start condition and shift the next eight bits (the 7-bit address plus the R/W bit) MSB first. The device that recognizes the transmitted address responds by pulling the data line low during the ninth clock pulse. The device address is determined by the state of the ADDR pin. This ninth bit is known as an acknowledge bit. All other devices withdraw from the bus at this point and return to the idle condition. The R/W bit determines the direction of the data. A Logic 0 on the LSB of the first byte means that the master writes information to the peripheral, whereas a Logic 1 means that the master reads information from the peripheral after writing the subaddress and repeating the start address. A data transfer takes place until a stop condition is encountered. A stop condition occurs when SDA transitions from low to high while SCL is held high. The timing for the I<sup>2</sup>C port is shown in Figure 3.

Stop and start conditions can be detected at any stage during the data transfer. If these conditions are asserted out of sequence with normal read and write operations, the **SSM2518** immediately jumps to the idle condition. During a given SCL high period, the user should issue only one start condition, one stop condition, or a single stop condition followed by a single start condition. If an invalid subaddress is issued by the user, the **SSM2518** does not issue an acknowledge and returns to the idle condition. If the user exceeds the highest subaddress while in auto-increment mode, one of two actions is taken. In read mode, the **SSM2518** outputs the highest subaddress register contents until the master device issues a no acknowledge, indicating the end of a read. A no acknowledge condition is where the SDA line is not pulled low on the ninth clock pulse of SCL. If the highest subaddress location is reached while in write mode, the data for the invalid byte is not loaded into any subaddress register, a no acknowledge is issued by the **SSM2518**, and the part returns to the idle condition.

### I<sup>2</sup>C Read and Write Operations

Figure 33 shows the timing of a single word write operation. Every ninth clock, the **SSM2518** issues an acknowledge by pulling SDA low.

Figure 34 shows the timing of a burst mode write sequence. This figure shows an example where the target destination registers are two bytes. The **SSM2518** knows to increment its subaddress register every byte because the requested subaddress corresponds to a register or memory area with a byte word length.

The timing of a single word read operation is shown in Figure 35. Note that the first R/W bit is 0, indicating a write operation. This is because the subaddress still needs to be written to set up the internal address. After the **SSM2518** acknowledges the receipt of the subaddress, the master must issue a repeated start command followed by the chip address byte with the R/W bit set to 1 (read). This causes the **SSM2518** SDA to reverse and begin driving data back to the master. The master then responds every ninth pulse with an acknowledge pulse to the **SSM2518**.

Figure 36 shows the timing of a burst mode read sequence. This figure shows an example where the target destination registers are two bytes. The **SSM2518** knows to increment its subaddress register every byte because the requested subaddress corresponds to a register or memory area with a byte word length.

**VOLUME AND MUTE CONTROL REGISTER**

Address: 0x07, Reset: 0x81, Name: Volume\_Mute\_Control

Table 20. Bit Descriptions for Volume\_Mute\_Control

Bits	Bit Name	Settings	Description	Reset	Access
7	AMUTE	0 1	Automatic Mute Enable. After 2048 slots (1024 stereo samples) have been received with zero data, the outputs mute until nonzero data arrives. Automute enabled Automute disabled	0x1	RW
6	RESERVED		Reserved.	0x0	RW
5	ANA_GAIN	0 1	Analog Gain. This sets the full-scale output level of the amplifier. The two settings are scaled appropriately for 3.6 V and 5.0 V nominal supply voltages. Matched to 3.6 V supply Matched to 5.0 V supply	0x0	RW
4	DEEMP_EN	0 1	Digital De-Emphasis Filter. De-emphasis disabled (normal operation) De-emphasis enabled	0x0	RW
3	VOL_LINK	0 1	Volume Link. When this bit is enabled, both channels respond to the left channel volume register. Normal operation Both channels linked to L_VOL (Register 0x05)	0x0	RW
2	R_MUTE	0 1	Right Channel Soft Mute. Normal operation Right channel muted	0x0	RW
1	L_MUTE	0 1	Left Channel Soft Mute. Normal operation Left channel muted	0x0	RW
0	M_MUTE	0 1	Master Mute Control. This bit soft mutes both channels. Normal operation Master mute	0x1	RW

**FAULT CONTROL 1 REGISTER**

Address: 0x08, Reset: 0x0C, Name: Fault\_Control\_1

Table 21. Bit Descriptions for Fault\_Control\_1

Bits	Bit Name	Settings	Description	Reset	Access
7	OC_L	0 1	Left Channel Overcurrent Fault. Read only. Normal operation Left channel overcurrent fault	0x0	R
6	OC_R	0 1	Right Channel Overcurrent Fault. Read only. Normal operation Right channel overcurrent fault	0x0	R
5	OT	0 1	Overtemperature Fault Status. Read only. Normal operation Overtemperature fault	0x0	R
4	MRCV	0 1	Manual Fault Recovery. Available only when ARCV = 11. Write only. Normal operation When written, attempt a manual fault recovery	0x0	W
[3:2]	MAX_AR	00 01 10 11	Maximum Fault Recovery Attempts. One attempt Three attempts Seven attempts Unlimited attempts	0x3	RW
[1:0]	ARCV	00 01 10 11	Automatic Fault Recovery Selection. Automatically recover from overtemperature and overcurrent faults Automatically recover from overtemperature fault only Automatically recover from overcurrent faults only No automatic recovery	0x0	RW

**POWER AND FAULT CONTROL REGISTER**

Address: 0x09, Reset: 0x99, Name: Power\_Fault\_Control

Table 22. Bit Descriptions for Power\_Fault\_Control

Bits	Bit Name	Settings	Description	Reset	Access
[7:6]	AR_TIME	00 01 10 11	Automatic Recovery Delay Time. This determines the amount of time delay between fault detection and an autorecovery attempt. 10 ms autorecovery delay 20 ms autorecovery delay 40 ms autorecovery delay 80 ms autorecovery delay	0x2	RW
5	RESERVED		Reserved.	0x0	RW
4	AMP_LPM	0 1	Class-D Amplifier Low Power Mode. High performance operation Low power operation	0x1	RW
3	DAC_LPM	0 1	DAC Low Power Mode. In low power mode, the DAC runs at half speed. Normal operation Low power operation	0x1	RW
2	R_PWDN	0 1	Right Channel Power-Down. Normal operation Right channel powered down	0x0	RW
1	L_PWDN	0 1	Left Channel Power-Down. Normal operation Left channel powered down	0x0	RW
0	APWDN_EN	0 1	Automatic Power-Down Enable. Automatic power-down automatically puts the IC in a low power state when 2048 consecutive zero input samples have been received. Automatic power-down disabled Automatic power-down enabled	0x1	RW

**DRC CONTROL 1 REGISTER**

Address: 0x0A, Reset: 0x7C, Name: DRC\_Control\_1

**Table 23. Bit Descriptions for DRC\_Control\_1**

Bits	Bit Name	Settings	Description	Reset	Access
7	RESERVED		Reserved.	0x0	RW
6	PRE_VOL	0 1	DRC Placement. This determines the placement of the DRC block in the signal chain. When placed before the volume control, the thresholds are relative to the input signal. When placed after the volume control, the thresholds are relative to the output signal level. All thresholds are 6 dB higher when placed after the volume control. 0 DRC operates after the volume control 1 DRC operates before the volume control	0x1	RW
5	LIM_EN	0 1	Limiter Enable. With the limiter enabled, the DRC_LT threshold (Bits[7:4] in Register 0x0C) must be set. 0 Limiter disabled 1 Limiter enabled	0x1	RW
4	COMP_EN	0 1	Compressor Enable. With the compressor enabled, the DRC_CT and DRC_SMAX thresholds (Bits[3:0] in Register 0x0C and Bits[7:4] in Register 0x0E) must be set. 0 Compressor disabled 1 Compressor enabled	0x1	RW
3	EXP_EN	0 1	Expander Enable. With the expander enabled, the DRC_ET and DRC_SMIN threshold values (Bits[7:4] in Register 0x0D and Bits[3:0] in Register 0x0E) must be set. 0 Expander disabled 1 Expander enabled	0x1	RW
2	NG_EN	0 1	Noise Gate Enable. With the noise gate enabled, the DRC_NT threshold value (Bits[3:0] in Register 0x0D) must be set. 0 Noise gate disabled 1 Noise gate enabled	0x1	RW
[1:0]	DRC_EN	00 01 10 11	Master DRC Enable. This must be enabled for any of the DRC features to function. 00 DRC disabled 01 Left channel DRC enabled 10 Right channel DRC enabled 11 Left and right channel DRC enabled	0x0	RW

This is the averaging time for the rms level that is compared to the DRC thresholds.	0x7	RW

# PACKAGING AND ORDERING INFORMATION

## OUTLINE DIMENSIONS

05-19-2011-A

Figure 37.16-Ball Wafer Level Chip Scale Package [WLCSP] (CB-16-13)

Dimensions shown in millimeters

061609-B

COMPLIANT TO JEDEC STANDARDS MO-220-WGGD.

Figure 38. 20-Lead Lead Frame Chip Scale Package [LF CSP\_WQ]

4 mm x 4 mm Body, Very Very Thin Quad (CP-20-10)

Dimensions shown in millimeters

**ORDERING GUIDE**

Model <sup>1</sup>	Temperature Range	Package Description	Package Option
SSM2518CBZ-RL	−40°C to +85°C	16-Ball, 2.2 mm × 2.2 mm WLCSP	CB-16-13
SSM2518CBZ-R7	−40°C to +85°C	16-Ball, 2.2 mm × 2.2 mm WLCSP	CB-16-13
SSM2518CPZ	−40°C to +85°C	20-Lead 4 mm × 4 mm LFCSP	CP-20-10
SSM2518CPZ-R7	−40°C to +85°C	20-Lead 4 mm × 4 mm LFCSP	CP-20-10
SSM2518CPZ-RL	−40°C to +85°C	20-Lead 4 mm × 4 mm LFCSP	CP-20-10
EVAL-SSM2518Z		Evaluation Board	

<sup>1</sup> Z = RoHS Compliant Part.
